I. INTRODUCTION

The transient heat fluxes and electromagnetic stresses that the plasma facing components would experience during a disruption in a tokamak fusion reactor are unacceptably large.^{1,2} Hence, such a reactor must be capable of reliably operating in an essentially disruption-free manner. Disruptions in tokamaks are triggered by macroscopic magnetohydrodynamical (MHD) instabilities.³ Fortunately, disruptions associated with ideal and “classical” tearing instabilities can be readily avoided by keeping the toroidal plasma current, the mean plasma pressure, and the mean electron number density below critical values that are either easily calculable or well-known empirically.¹

A tearing mode⁴ of finite amplitude generates a helical magnetic island chain⁵ in the vicinity of the rational surface⁶ at which it reconnects magnetic flux. If the radial width of the island chain exceeds a relatively small threshold value then fast parallel heat transport causes a local flattening of the electron temperature profile within the chain’s magnetic separatrix.⁷ The associated loss of the pressure-gradient-driven non-inductive neoclassical bootstrap current⁸ within the separatrix has a destabilizing effect that can render a linearly-stable tearing mode unstable at finite amplitude. This type of instability is known as a “neoclassical tearing mode” (NTM). All reactor-relevant tokamak discharges are potentially unstable to 2/1 and 3/2 NTMs.^{9,10} (Here, m/n denotes a mode whose resonant harmonic has m periods in the poloidal direction, and n periods in the toroidal direction.) It is, therefore, not surprising that NTMs are, by far, the most common cause of disruptions in high-performance tokamak discharges.^{1,9,10} Now, an NTM needs to exceed a critical threshold amplitude before it is triggered. In practice, NTMs are triggered by transient magnetic perturbations associated with other more benign instabilities in the plasma, such as sawtooth oscillations, and edge localized modes (ELMs).^{9,10} NTMs pose a unique challenge to tokamak fusion reactors because all reactor-relevant tokamak discharges are potentially unstable to multiple NTMs. Moreover, NTM onset is essentially unpredictable, because it is impossible to determine ahead of time which particular sawtooth crash or ELM is going to trigger a particular NTM. Indeed, not all previously documented NTMs possess identifiable triggers.¹¹

Neoclassical tearing modes can be suppressed via electron cyclotron current drive (ECCD).¹²

This technique, which has been successfully implemented on many tokamaks,^{13–17} involves launching electron cyclotron waves into the plasma in such a manner that they drive a toroidal current (in the same direction as the equilibrium current) that is localized inside the magnetic separatrix of the NTM island chain. The ideal is to compensate for the loss of the bootstrap current inside the separatrix consequent on the local flattening of the electron temperature profile.^{9,10}

The successful suppression of an NTM via ECCD depends crucially on the early detection of the mode, combined with an accurate measurement of the instantaneous location of, at least, one of the O-points of the associated island chain.¹⁸ In fact, because the island chain is radially thin, but relatively extended in poloidal and toroidal angle, the measurement of the radial location of the O-point is, by far, the most difficult aspect of this process. The most accurate method of determining the radial location of the O-point is to measure the temperature fluctuations associated with the island chain by means of electron cyclotron emission (ECE) radiometry.^{7,19–21}

Given the crucial importance of early and accurate detection of NTMs via ECE radiometry to the success of tokamak fusion reactors, existing theoretical calculations of the expected ECE signal, which are based on single-harmonic cylindrical theory, are surprisingly primitive.^{18,21,22} The aim of this paper is to improve such calculations by taking into account the fact that an NTM in a realistic toroidal tokamak equilibrium consists of multiple coupled poloidal and toroidal harmonics. Harmonics with the same toroidal mode number as the NTM, but different poloidal mode numbers, are linearly coupled by the Shafranov shifts, elongations, and triangularities of the equilibrium magnetic flux-surfaces.^{23–25} Furthermore, harmonics whose poloidal and toroidal mode numbers are in the same ratio as those of the NTM are coupled nonlinearly in the immediate vicinity of the island chain.^{5,7} Previous calculations have taken into account the important fact that the island chain is radially asymmetric with respect to the rational surface,²⁶ due to the mean radial gradient of the tearing eigenfunction at the surface, but have not necessarily make an accurate determination the asymmetry.¹⁸ Our improved calculation incorporates an accurate assessment of the asymmetry. Finally, ECE emission is downshifted and broadened in frequency due to the relativistic mass increase of the emitting electrons.^{19,20,27} This process leads to a shift in

the inferred location of the ECE emission to larger major radius, as well as a radial smearing out the emission. Both of these effects, which limit the accuracy to which the radial location of the island O-point can be measured via ECE emission, are taken into account in our improved calculation.

The calculation of the magnetic perturbation associated with an NTM is most efficiently formulated as an asymptotic matching problem in which the plasma is divided into two distinct regions.^{4,23–25,28–33} In the “outer region”, which comprises most of the plasma, the perturbation governed by the equations of linearized, marginally-stable, ideal-MHD. However, these equations become singular on “rational” magnetic flux-surfaces at which the perturbed magnetic field resonates with the equilibrium field. In the “inner region”, which consists of a set of narrow layers centered on the various rational surfaces, non-ideal-MHD effects such as plasma resistivity, as well as nonlinear effects, become important. In the calculation described in this paper, the NTM is assumed to reconnect magnetic flux at one particular rational surface in the plasma (i.e., the $q = 2$ surface for the case of a 2/1 mode, and the $q = 3/2$ surface in the case of a 3/2 mode). The response of the plasma at the other rational surfaces is assumed to be ideal, as we would expect to be the case in the presence of sheared plasma rotation.²⁵ The magnetic perturbation in the segment of the inner region centered on the reconnecting rational surface is that associated with a radially asymmetric magnetic island chain.^{5,34} The nonlinear island solution needs to be asymptotically matched to the ideal-MHD solution in the outer region. The temperature perturbation associated with the NTM in the inner and outer regions is simultaneously determined by the asymptotic matching process.

In this paper, the asymptotic matching is performed using the TJ toroidal tearing mode code,^{32,33} which employs an aspect-ratio expanded toroidal magnetic equilibrium.³⁵ The TJ code is used for the sake of convenience. However, the calculations described in this paper could just as well be implemented in a toroidal tearing mode code, such as STRIDE,^{30,31} that employs a general toroidal magnetic equilibrium.

II. PLASMA EQUILIBRIUM

A. Normalization

Unless otherwise specified, all lengths in this paper are normalized to the major radius of the plasma magnetic axis, R_0 . All magnetic field-strengths are normalized to the toroidal field-strength at the magnetic axis, B_0 . All plasma pressures are normalized to B_0^2/μ_0 .

B. Coordinates

Let R, ϕ, Z be right-handed cylindrical coordinates whose symmetry axis corresponds to the symmetry axis of the axisymmetric toroidal plasma equilibrium. Let r, θ, ϕ be right-handed flux-coordinates whose Jacobian is

$$\mathcal{J}(r, \theta) \equiv (\nabla r \times \nabla \theta \cdot \nabla \phi)^{-1} = r R^2. \quad (1)$$

Note that $r = r(R, Z)$ and $\theta = \theta(R, Z)$. The magnetic axis corresponds to $r = 0$, and the plasma-vacuum interface to $r = a$. Here, $a \ll 1$ is the effective inverse aspect-ratio of the plasma.

C. Equilibrium Magnetic Field

Consider a tokamak plasma equilibrium whose magnetic field takes the form

$$\mathbf{B}(r, \theta) = f(r) \nabla \phi \times \nabla r + g(r) \nabla \phi = f \nabla(\phi - q \theta) \times \nabla r, \quad (2)$$

where $q(r) = r g/f$ is the safety-factor profile. Equilibrium force balance requires that $\nabla P = \mathbf{J} \times \mathbf{B}$, where

$$P(r) = a^2 p_2(r), \quad (3)$$

is the equilibrium scalar plasma pressure profile, and $\mathbf{J} = \nabla \times \mathbf{B}$ the equilibrium plasma current density. The (unnormalized) equilibrium electron temperature profile is written

$$T_{e0}(r) = \frac{B_0^2}{\mu_0} \frac{P(r)}{2 n_e(r)} + T_{e\text{ped}}, \quad (4)$$

where $n_e(r)$ is the (unnormalized) equilibrium electron number density profile. Here, we are assuming that the electrons and ions have the same temperature, as is likely to be the case in a tokamak fusion reactor.

D. Equilibrium Magnetic Flux-Surfaces

The loci of the up-down symmetric equilibrium magnetic flux-surfaces are written in the parametric form²⁵

$$R(\hat{r}, \omega) = 1 - a \hat{r} \cos \omega + a^2 [H_1(\hat{r}) \cos \omega + H_2(\hat{r}) \cos 2\omega + H_3(\hat{r}) \cos 3\omega], \quad (5)$$

$$Z(\hat{r}, \omega) = a \hat{r} \sin \omega + a^2 [H_2(\hat{r}) \sin 2\omega + H_3(\hat{r}) \sin 3\omega], \quad (6)$$

where $r = a \hat{r}$. Here, $H_1(\hat{r})$, $H_2(\hat{r})$, and $H_3(\hat{r})$ control the Shafranov shifts, vertical elongations, and triangularities of the flux-surfaces, respectively. Moreover,³⁵

$$g(\hat{r}) = 1 + a^2 g_2(\hat{r}), \quad (7)$$

$$g'_2 = -p'_2 - \frac{\hat{r}}{q^2} (2 - s), \quad (8)$$

$$H''_1 = -(3 - 2s) \frac{H'_1}{\hat{r}} - 1 + \frac{2p'_2 q^2}{\hat{r}}, \quad (9)$$

$$H''_j = -(3 - 2s) \frac{H'_j}{\hat{r}} + (j^2 - 1) \frac{H_j}{\hat{r}^2} \quad \text{for } j > 1, \quad (10)$$

$$\theta = \omega + a \hat{r} \sin \omega - a \sum_{j=1,3} \frac{1}{j} \left[H'_j - (j - 1) \frac{H_j}{\hat{r}} \right] \sin j \omega, \quad (11)$$

where $s(\hat{r}) = \hat{r} q' / q$ is the magnetic shear, and $'$ denotes $d/d\hat{r}$. The plasma equilibrium is fully specified by the value of a , the two free flux-surface functions $q(\hat{r})$ and $p_2(\hat{r})$, and the values of $H_2(1)$ and $H_3(1)$.

III. ELECTRON TEMPERATURE PERTURBATION IN OUTER REGION

A. Perturbation in Outer Region

Let the positive integer n be the toroidal mode number of the NTM. Let there be K rational surfaces in the plasma, of radius r_k (for $k = 1, K$), at which the resonance condition

$q(r_k) = m_k/n$ is satisfied, where the positive integer m_k is the resonant poloidal mode number at the k th surface. The perturbed magnetic field in the outer region is specified by^{32,33}

$$b^r(r, \theta, \phi) \equiv \mathbf{b} \cdot \nabla r = \frac{i}{r R^2} \sum_{j=1, J} \psi_{m_j}(r) e^{i(m_j \theta - n \phi)}. \quad (12)$$

Here, \mathbf{b} is the perturbed magnetic field-strength, and the m_j are the poloidal mode numbers included in the calculation. (The m_k are a subset of the m_j .)

The functions $\psi_{m_j}(r)$ are determined by solving a set of $2J$ coupled ordinary differential equations that are singular at the various rational surfaces in the plasma. The solutions to these equations must be launched from the magnetic axis ($r = 0$), integrated outward in r , stopped and just before and restarted just after each rational surface in the plasma, integrated to the plasma boundary ($r = a$), and then matched to a free-boundary vacuum solution. This process is described in detail in Ref. 32.

B. Behavior in Vicinity of Rational Surface

Consider the behavior of the $\psi_{m_j}(r)$ in the vicinity of the k th rational surface. The non-resonant $\psi_{m_j}(r)$, for which $m_j \neq m_k$, are continuous across the surface. On the other hand, the resonant $\psi_{m_k}(r)$ is such that

$$\psi_{m_k}(r_k + x) = A_{Lk} |x|^{\nu_{Lk}} + \text{sgn}(x) A_{Sk}^{\pm} |x|^{\nu_{Sk}}, \quad (13)$$

$$(14)$$

where

$$\nu_{Lk} = \frac{1}{2} - \sqrt{-D_{Ik}}, \quad (15)$$

$$\nu_{Sk} = \frac{1}{2} + \sqrt{-D_{Ik}}, \quad (16)$$

$$D_{Ik} = - \left[\frac{2(1 - q^2)}{s^2} r \frac{dP}{dr} \right]_{r_k} - \frac{1}{4}, \quad (17)$$

$$L_{m_k}^{m_k}(r) = m_k^2 c_{m_k}^{m_k}(r) + n^2 r^2, \quad (18)$$

$$c_{m_k}^{m_k}(r) = \oint |\nabla r|^{-2} \frac{d\theta}{2\pi}. \quad (19)$$

Here, A_{Lk} is termed the coefficient of the “large” solution, whereas A_{Sk} is the coefficient of the “small” solution. Furthermore, D_{Ik} is the ideal Mercier interchange parameter (which needs to be negative to ensure stability to localized interchange modes),^{36–38} and ν_{Lk} and ν_{Sk} are termed the Mercier indices.

It is helpful to define the quantities³²

$$\Psi_k = r_k^{\nu_{Lk}} \left(\frac{\nu_{Sk} - \nu_{Lk}}{L_{m_k}^{m_k}} \right)^{1/2}_{r_k} A_{Lk}, \quad (20)$$

$$\Delta\Psi_k = r_k^{\nu_{Sk}} \left(\frac{\nu_{Sk} - \nu_{Lk}}{L_{m_k}^{m_k}} \right)^{1/2}_{r_k} (A_{Sk}^+ - A_{Sk}^-), \quad (21)$$

at each rational surface in the plasma. Here, the complex parameter Ψ_k is a measure of the reconnected helical magnetic flux at the k th rational surface, whereas the complex parameter $\Delta\Psi_k$ is a measure of the strength of a localized current sheet that flows parallel to the equilibrium magnetic field at the surface.

It is assumed that $\Psi_k = 0$ for all k , except for $k = l$. In other words, the NTM only reconnects magnetic flux at the l th rational surface. Let

$$\psi_{m_j}(r) = \Psi \hat{\psi}_{m_j}(r), \quad (22)$$

where Ψ is the reconnected magnetic flux at the l th rational surface, and the $\hat{\psi}_{m_j}(r)$ are normalized such that $\Psi_k = \delta_{kl}$.

C. Electron Temperature in Outer Region

Let $\xi(r, \theta, \phi)$ be the plasma displacement in the outer region. We can write³³

$$\begin{aligned} \xi^r(r, \theta, \phi) &\equiv \xi \cdot \nabla r = \sum_{j=1, J} \xi_{m_j}^r(r) e^{i(m_j \theta - n \phi)} \\ &= \Psi \frac{q}{r g} \sum_{j=1, J} \frac{\hat{\psi}_{m_j}}{m_j - n q} e^{i(m_j \theta - n \phi)}. \end{aligned} \quad (23)$$

The perturbed electron temperature in the outer region is written

$$\delta T_e(r, \theta, \phi) = -\frac{dT_{e0}}{dr} \xi^r(r, \theta, \phi) + \delta T_{e0} H(r - r_l) \quad (24)$$

where

$$H(x) = \begin{cases} 1 & x < 0 \\ 0 & x > 0 \end{cases}. \quad (25)$$

Here, we are assuming that the electron temperature is passively convected by the plasma in the outer region. We are also assuming that there is no change in topology of the magnetic flux-surfaces in the outer region. In other words, any topology changes are confined to the inner region. Finally, δT_{e0} is the reduction in the equilibrium electron temperature in the plasma core due to the flattening of the temperature profile in the vicinity of the NTM island chain.³⁹

IV. ELECTRON TEMPERATURE PERTURBATION IN INNER REGION

A. Introduction

Consider the segment of the inner region in the vicinity of the l th rational surface, where the NTM reconnects magnetic flux. Let $x = r - r_l$, $X = x/W$, and $\zeta = m_l \theta - n \phi$, where W is the full width of the magnetic separatrix of the NTM island chain. Let search for a single-helicity solution in which the magnetic flux-surfaces in the vicinity of the island chain are contours of $\Omega(X, \zeta)$. Now, a magnetic island chain is a helical magnetic equilibrium.⁵ As such, the island magnetic-flux surfaces must satisfy the fundamental force balance requirement³⁴

$$\left[\frac{\partial^2 \Omega}{\partial X^2} \Big|_{\zeta}, \Omega \right] = 0, \quad (26)$$

where

$$[A, B] \equiv \frac{\partial A}{\partial X} \Big|_{\zeta} \frac{\partial B}{\partial \zeta} \Big|_X - \frac{\partial B}{\partial X} \Big|_{\zeta} \frac{\partial A}{\partial \zeta} \Big|_X. \quad (27)$$

B. Island Magnetic Flux-Surfaces

A suitable solution of Eq. (26) that connects to the ideal-MHD solution in the outer region is³⁴

$$\Omega(X, \zeta) = 8 X^2 + \cos(\zeta - \delta^2 \sin \zeta) - 2\sqrt{8} \delta X \cos \zeta + \delta^2 \cos^2 \zeta, \quad (28)$$

where $|\delta| < 1$. As illustrated in Fig. 1, the magnetic flux-surfaces (i.e., the contours of Ω) map out an asymmetric (with respect to $X = 0$) island chain whose X-points lie at $X = \delta/\sqrt{8}$, $\zeta = 0, 2\pi$, and $\Omega = +1$, and whose O-points lie at $X = -\delta/\sqrt{8}$, $\zeta = \pi$, and $\Omega = -1$. The maximum width of the magnetic separatrix (in x) is W .

The first term on the right-hand side of Eq. (28) emanates from the unperturbed (by the NTM) plasma equilibrium, whereas the remaining terms emanate from the NTM perturbation in the outer region. In particular, the third term on the right-hand side, which governs the island asymmetry, originates from the mean radial gradient in the $\cos \zeta$ component of the linear NTM eigenfunction at the rational surface.

The island asymmetry is governed by the dimensionless parameter δ . If $\delta > 0$ then the island O-points are displaced radially inward (with respect to the unperturbed rational surface), whereas the X-points are displaced radially outward an equal distance. The opposite is the case if $\delta < 0$. Generally speaking, we expect $\delta > 0$ for NTMs (because the linear eigenfunctions for such modes tend to attain their maximum amplitudes inside the rational surface; see Fig. 2 in Ref. 40). Note that if $|\delta|$ exceeds the critical value unity then the X-points bifurcate, and it is no longer possible to analyze the resistive evolution of the resulting island chain using a variant of standard Rutherford island theory.⁵ Hence, we shall only consider the case $-1 \leq \delta < 1$.

C. Coordinate Transformation

Let us define the new coordinates³⁴

$$Y = X - \frac{\delta}{\sqrt{8}} \cos \zeta, \quad (29)$$

$$\xi = \zeta - \delta^2 \sin \zeta. \quad (30)$$

When expressed in terms of these coordinates, the magnetic flux-function (28) reduces to the simple form

$$\Omega(Y, \xi) = 8Y^2 + \cos \xi. \quad (31)$$

Thus, as illustrated in Fig. 2, irrespective of the value of the asymmetry parameter, δ , when plotted in Y, ξ space, the magnetic flux-surfaces map out a symmetric (with respect to

$Y = 0$) island chain whose O-points lie at $\xi = \pi$, $Y = 0$, and $\Omega = -1$, and whose X-points lie at $\xi = 0, 2\pi$, $Y = 0$, and $\Omega = +1$.

The inversion of Eq. (30) is very well known:⁴¹

$$\zeta = \xi + 2 \sum_{n=1,\infty} \left[\frac{J_n(n\delta^2)}{n} \right] \sin(n\xi), \quad (32)$$

$$\cos \zeta = -\frac{\delta^2}{2} + \sum_{n=1,\infty} \left[\frac{J_{n-1}(n\delta^2) - J_{n+1}(n\delta^2)}{n} \right] \cos(n\xi), \quad (33)$$

$$\sin \zeta = \frac{2}{\delta^2} \sum_{n=1,\infty} \left[\frac{J_n(n\delta^2)}{n} \right] \sin(n\xi), \quad (34)$$

$$\cos(m\zeta) = m \sum_{n=1,\infty} \left[\frac{J_{n-m}(n\delta^2) - J_{n+m}(n\delta^2)}{n} \right] \cos(n\xi), \quad (35)$$

$$\sin(m\zeta) = m \sum_{n=1,\infty} \left[\frac{J_{n-m}(n\delta^2) + J_{n+m}(n\delta^2)}{n} \right] \cos(n\xi), \quad (36)$$

for $m > 1$.

D. Plasma Displacement

Outside the magnetic separatrix, we can write

$$\Omega(X, \zeta) = 8(X - \Xi)^2, \quad (37)$$

where $\Xi = \xi^r/W$ is the normalized radial plasma displacement. It follows that

$$\begin{aligned} \Xi(X, \zeta) &\simeq -\frac{[\Omega(X, \zeta) - 8X^2 - 8\Xi^2]}{16X} \\ &= -\frac{\cos(\zeta - \delta^2 \sin \zeta) + \delta^2 \cos^2 \zeta}{16X} + \frac{\delta}{\sqrt{8}} \cos \zeta + \frac{\Xi^2}{2X} \\ &\simeq -\frac{\cos(\zeta - \delta^2 \sin \zeta)}{16X} + \frac{\delta}{\sqrt{8}} \cos \zeta, \end{aligned} \quad (38)$$

where use has been made of Eq. (28). Note that $\Xi(X, \zeta)$ is an even function of ζ . Let us write

$$\Xi(X, \zeta) = \sum_{n=0,\infty} \Xi_n(X) \cos(n\zeta). \quad (39)$$

Thus,

$$\begin{aligned}
\Xi_1(X) &= 2 \oint \Xi(X, \zeta) \cos(\zeta) \frac{d\zeta}{2\pi} = -\frac{1}{8X} \oint \cos(\zeta - \delta^2 \sin \zeta) \cos \zeta \frac{d\zeta}{2\pi} + \frac{\delta}{\sqrt{8}} \\
&= -\frac{1}{16X} \oint \cos(-\delta^2 \sin \zeta) \cos \zeta \frac{d\zeta}{2\pi} \\
&\quad - \frac{1}{16X} \oint \cos(2\zeta - \delta^2 \sin \zeta) \cos \zeta \frac{d\zeta}{2\pi} + \frac{\delta}{\sqrt{8}}. \tag{40}
\end{aligned}$$

But,^{41,42}

$$J_n(\delta^2) = \oint \cos(n\zeta - \delta^2 \sin \zeta) \frac{d\zeta}{2\pi}, \tag{41}$$

so

$$\Xi_1(X) = -\frac{J_0(\delta^2) + J_2(\delta^2)}{16X} + \frac{\delta}{\sqrt{8}}, \tag{42}$$

and

$$\xi_1^r(r_l + x) = -\frac{W^2}{16x} [J_0(\delta^2) + J_2(\delta^2)] + \frac{W\delta}{\sqrt{8}}. \tag{43}$$

In the outer region, the equivalent quantity to $\xi_1^r(r)$ is $\xi_{m_l}^r(r)$. It follows from Eq. (23) that

$$\xi_{m_l}^r(r_l + x) = \Psi \frac{q}{r g} \frac{\hat{\psi}_{m_l}}{m_l - n q} = -\Psi \left(\frac{h q}{s q} \right)_{r_l} \frac{1}{x} + \mathcal{O}(1), \tag{44}$$

where

$$h(r) = \frac{(L_{m_l}^{m_l})^{1/2}}{m_l}, \tag{45}$$

and use has been made of Eqs. (13) and (20). Here, we are assuming that $\nu_{Ll} \simeq 0$ and $\nu_{Sl} \simeq 1$, as is generally the case in a large aspect-ratio tokamak. A comparison between Eqs. (43) and (44) reveals that

$$\Psi = \left(\frac{W}{4} \right)^2 \left(\frac{s g}{h q} \right)_{r_l} [J_0(\delta^2) + J_2(\delta^2)], \tag{46}$$

and

$$\delta \simeq \frac{\sqrt{2}}{W} [\xi_{m_l}^r(r_l + W) + \xi_{m_l}^r(r_l - W)]. \tag{47}$$

Equation (46) gives the relationship between the reconnected magnetic flux, Ψ , and the island width W . This relationship differs from the conventional one⁵ because of corrections due to the radial asymmetry of the island chain. However, the corrections are fairly minor.

In fact, $0.880 \leq J_0(\delta^2) + J_2(\delta^2) \leq 1$ for $0 \leq \delta \leq 1$. Equation (73) specifies the relationship between the island asymmetry parameter, δ , and the mean radial gradient in $\hat{\psi}_{m_l}(r)$ at the rational surface. Note that the matching between the inner and outer solutions is made at $r = r_l \pm W$.

E. Flux-Surface Average Operator

Now,

$$\left. \frac{\partial}{\partial X} \right|_{\zeta} = \left. \frac{\partial \Omega}{\partial X} \right|_{\zeta} \left. \frac{\partial}{\partial \Omega} \right|_{\xi} + \left. \frac{\partial \xi}{\partial X} \right|_{\zeta} \left. \frac{\partial}{\partial \xi} \right|_{\Omega} = 16 Y \left. \frac{\partial}{\partial \Omega} \right|_{\xi}, \quad (48)$$

and

$$\left. \frac{\partial}{\partial \zeta} \right|_X = \left. \frac{\partial \Omega}{\partial \zeta} \right|_X \left. \frac{\partial}{\partial \Omega} \right|_{\xi} + \left. \frac{\partial \xi}{\partial \zeta} \right|_X \left. \frac{\partial}{\partial \xi} \right|_{\Omega}, \quad (49)$$

so

$$[A, B] \equiv \frac{16 Y}{\sigma} \left(\left. \frac{\partial A}{\partial \Omega} \right|_{\xi} \left. \frac{\partial B}{\partial \xi} \right|_{\Omega} - \left. \frac{\partial B}{\partial \Omega} \right|_{\xi} \left. \frac{\partial A}{\partial \xi} \right|_{\Omega} \right), \quad (50)$$

where

$$\sigma(\xi) \equiv \frac{d\zeta}{d\xi} = 1 + 2 \sum_{n=1, \infty} J_n(n \delta^2) \cos(n \xi), \quad (51)$$

and use has been made of Eqs. (27) and (32). In particular,

$$[A, \Omega] = -\frac{16 Y}{\sigma} \left. \frac{\partial A}{\partial \xi} \right|_{\Omega}. \quad (52)$$

The flux-surface average operator, $\langle \cdots \rangle$, is the annihilator of $[A, \Omega]$ for arbitrary $A(s, \Omega, \xi)$.^{7,34} Here, $s = +1$ for $Y > 0$ and $s = -1$ for $Y < 0$. It follows that

$$\langle A \rangle = \int_{\zeta_0}^{2\pi - \zeta_0} \frac{\sigma(\xi) A_+(\Omega, \xi)}{\sqrt{2(\Omega - \cos \xi)}} \frac{d\xi}{2\pi} \quad (53)$$

for $-1 \leq \Omega \leq 1$, and

$$\langle A \rangle = \int_0^{2\pi} \frac{\sigma(\xi) A(s, \Omega, \xi)}{\sqrt{2(\Omega - \cos \xi)}} \frac{d\xi}{2\pi} \quad (54)$$

for $\Omega > 1$. Here, $\xi_0 = \cos^{-1}(\Omega)$, and

$$A_+(\Omega, \xi) = \frac{1}{2} [A(+1, \Omega, \xi) + A(-1, \Omega, \xi)]. \quad (55)$$

F. Wide Island Limit

In the so-called “wide island limit”, in which parallel electron heat transport dominates perpendicular heat transport,^{7,34} the electron temperature in the vicinity of the island chain can be written

$$T_e(X, \zeta) = T_{el} + s W T'_{el} \tilde{T}(\Omega), \quad (56)$$

where $T_{el} = T_{e0}(r_l)$ and $T'_{el} = dT_{e0}(r_l)/dr$. Here, $\tilde{T}(\Omega)$ satisfies⁷

$$\left\langle \frac{\partial^2 \tilde{T}}{\partial X^2} \right|_{\zeta} = 0, \quad (57)$$

subject to the boundary condition that

$$\tilde{T}(\Omega) \rightarrow |X| \quad (58)$$

as $|X| \rightarrow \infty$. It follows from Eqs. (31), (48), and (54) that

$$\frac{d}{d\Omega} \left(\langle Y^2 \rangle \frac{d\tilde{T}}{d\Omega} \right) = 0 \quad (59)$$

subject to the boundary condition that

$$\tilde{T}(\Omega) \rightarrow \frac{\Omega^{1/2}}{\sqrt{8}} \quad (60)$$

as $\Omega \rightarrow \infty$. Note that $\tilde{T} = 0$ inside the magnetic separatrix, by symmetry.⁷

Outside the separatrix,

$$\langle Y^2 \rangle(\Omega) = \frac{1}{16} \int_0^{2\pi} \sigma(\xi) \sqrt{2(\Omega - \cos \xi)} \frac{d\xi}{2\pi}. \quad (61)$$

Let

$$\kappa = \left(\frac{1 + \Omega}{2} \right)^{1/2}. \quad (62)$$

Thus, the O-points correspond to $\kappa = 0$ and the magnetic separatrix to $\kappa = 1$. It follows that

$$\langle Y^2 \rangle(\kappa) = \frac{\kappa}{4\pi} \int_0^{\pi/2} \sigma(2\vartheta - \pi) \left(1 - \frac{\sin^2 \vartheta}{\kappa^2} \right)^{1/2} d\vartheta. \quad (63)$$

Thus,

$$\langle Y^2 \rangle(\kappa) = \frac{\kappa}{4\pi} G(1/\kappa), \quad (64)$$

where

$$G(p) = E_0(p) + 2 \sum_{n=1, \infty} \cos(n\pi) J_n(n\delta^2) E_n(p), \quad (65)$$

$$E_n(p) = \int_0^{\pi/2} \cos(2n\vartheta) (1 - p^2 \sin^2 \vartheta)^{1/2} d\vartheta. \quad (66)$$

Equation (59) yields

$$\tilde{T}(\kappa) = 0 \quad (67)$$

for $0 \leq \kappa \leq 1$, and

$$\frac{d}{d\kappa} \left[G(1/\kappa) \frac{d\tilde{T}}{d\kappa} \right] = 0 \quad (68)$$

for $\kappa > 1$. Thus,

$$\frac{d\tilde{T}}{d\kappa} = \frac{c}{G(1/\kappa)} \quad (69)$$

for $\kappa > 1$, subject to the boundary condition that

$$\tilde{T}(\kappa) \rightarrow \frac{\kappa}{2} \quad (70)$$

as $\kappa \rightarrow \infty$. In the limit that $p \rightarrow 0$,

$$E_0(p) = \frac{\pi}{2}, \quad (71)$$

$$E_{n>0}(p) = 0, \quad (72)$$

which implies that $c = \pi/4$. So

$$\frac{d\tilde{T}}{d\kappa} = \frac{\pi}{4} \frac{1}{G(1/\kappa)}, \quad (73)$$

$$\tilde{T}(\kappa) = F(\kappa), \quad (74)$$

$$F(\kappa) = \frac{\pi}{4} \int_1^\kappa \frac{d\kappa'}{G(1/\kappa')} \quad (75)$$

for $\kappa > 1$.

V. HELICAL HARMONICS OF TEMPERATURE PERTURBATION

We can write

$$\tilde{T}(X, \zeta) = \sum_{\nu=0, \infty} \delta T_\nu(X) \cos(\nu \zeta). \quad (76)$$

Now,

$$\delta T_0(X) = \oint \tilde{T}(X, \zeta) \frac{d\zeta}{2\pi}, \quad (77)$$

where the integral is taken at constant X . It follows from Eqs. (31), (51), (62), and (74) that

$$\delta T_0(X) = \int_0^{\xi_c} F(\kappa) \sigma(\xi) \frac{d\xi}{\pi}, \quad (78)$$

where

$$\xi_c = \cos^{-1}(1 - 8Y^2) \quad (79)$$

for $|Y| < 1/2$, and $\xi_c = \pi$ for $|Y| \geq 1/2$. Furthermore,

$$\kappa = \left[4Y^2 + \cos^2\left(\frac{\xi}{2}\right) \right]^{1/2}. \quad (80)$$

Let

$$\delta T_{0\infty} = \lim_{X \rightarrow \infty} [X - \delta T_0(X)]. \quad (81)$$

For $\nu > 0$, we have

$$\delta T_\nu(X) = 2 \oint \tilde{T}(X, \zeta) \cos(\nu \zeta) \frac{d\zeta}{2\pi}. \quad (82)$$

Integrating by parts, we obtain

$$\delta T_\nu(X) = -\frac{2}{\nu} \oint \left. \frac{\partial \tilde{T}}{\partial \zeta} \right|_X \sin(\nu \zeta) \frac{d\zeta}{2\pi}. \quad (83)$$

But,

$$\left. \frac{\partial \tilde{T}}{\partial \zeta} \right|_X = \frac{d\tilde{T}}{d\kappa} \left. \frac{\partial \kappa}{\partial \zeta} \right|_X = \frac{1}{4\kappa} \frac{d\tilde{T}}{d\kappa} \left. \frac{\partial \Omega}{\partial \zeta} \right|_X = -\frac{1}{4\kappa} \frac{d\tilde{T}}{d\kappa} \tau(\xi), \quad (84)$$

where

$$\tau(\xi) = \sin \xi (1 - \delta^2 \cos \zeta) - 2\sqrt{8} \delta X \sin \zeta + \delta^2 \sin(2\zeta), \quad (85)$$

and use has been made of Eqs. (28) and (62). Hence,

$$\delta T_\nu(X) = \frac{1}{8\nu} \int_0^{\xi_c} \frac{\sin(\nu \zeta) \tau(\xi) \sigma(\xi)}{\kappa G(1/\kappa)} d\xi, \quad (86)$$

where use has been made of Eqs. (51) and (73).

FIG. 1. The thin solid curves show the contours of $\Omega(X, \zeta)$ evaluated for $\delta = 0.5$. The thick solid lines show the magnetic separatrix (upper and lower curves) and the contour $Y = 0$ (middle curve). The curved dotted lines show equally-spaced contours of Y , whereas the vertical dotted lines show equally-spaced contours of ξ .

FIG. 2. The thin solid curves show the contours of $\Omega(Y, \xi)$ evaluated for $\delta = 0.5$. The thick solid lines show the magnetic separatrix (upper and lower curves) and the contour $Y = 0$ (middle curve).
